### REC\_Python\_Week 3\_CY

Attempt : 1  
Total Mark : 30  
Marks Obtained : 30

### Section 1 : Coding

#### 1. Problem Statement

A company is creating email accounts for its new employees. They want to use a naming convention for email addresses that consists of the first letter of the employee's first name, followed by their last name, followed by @company.com.

The company also has a separate email domain for administrative employees.

Write a program that prompts the user for their first name, last name, role, and company and then generates their email address using the appropriate naming convention based on their role. This is demonstrated in the below examples.

Note:

The generated email address should consist of the first letter of the first name, the last name in lowercase, and a suffix based on the role and company, all in lowercase.

### ***Input Format***

The first line of input consists of the first name of an employee as a string.

The second line consists of the last name of an employee as a string.

The third line consists of the role of the employee as a string.

The last line consists of the company name as a string.

### ***Output Format***

The output consists of a single line containing the generated email address for the employee, following the specified naming convention.

Refer to the sample output for the formatting specifications.

### ***Sample Test Case***

Input: John

Smith

admin

iamNeo

Output: jsmith@admin.iamneo.com

### ***Answer***

```
first_name = input().strip()
```

```
last_name = input().strip()
```

```
role = input().strip().lower()
```

```
company = input().strip().lower()
```

```
email_local = first_name[0].lower() + last_name.lower()
```

```
if role == "admin":
```

```
    domain = f"{role}.{company}.com"
```

```
else:
```

```
    domain = f"{company}.com"
```

```
print(f"{email_local}@{domain}")
```

**Status :** Correct

**Marks :** 10/10

## 2. Problem Statement

You have two strings str1 and str2, both of equal length.

Write a Python program to concatenate the two strings such that the first character of str1 is followed by the first character of str2, the second character of str1 is followed by the second character of str2, and so on.

For example, if str1 is "abc" and str2 is "def", the output should be "adbecf".

### **Input Format**

The input consists of two strings in each line.

### **Output Format**

The output displays the concatenated string in the mentioned format.

Refer to the sample output for formatting specifications.

### **Sample Test Case**

Input: abc

def

Output: adbecf

### **Answer**

```
s1 = input()
s2 = input()
res = ".join(s1[i] + s2[i] for i in range(len(s1)))
print(res)
```

**Status :** Correct

**Marks :** 10/10

### 3. Problem Statement

Emily is a data analyst working for a company that collects feedback from customers in the form of text messages. As part of her data validation tasks, Emily needs to perform two operations on each message:

Calculate the sum of all the digits mentioned in the message. If the sum of the digits is greater than 9, check whether the sum forms a palindrome number.

Your task is to help Emily automate this process by writing a program that extracts all digits from a given message, calculates their sum, and checks if the sum is a palindrome if it is greater than 9.

#### ***Input Format***

The input consists of a string *s*, representing the customer message, which may contain letters, digits, spaces, and other characters.

#### ***Output Format***

The output prints an integer representing the sum of all digits in the string, followed by a space.

If the sum is greater than 9, print "Palindrome" if the sum is a palindrome, otherwise print "Not palindrome".

If the sum is less than or equal to 9, no palindrome check is required.

Refer to the sample output for the formatting specifications.

#### ***Sample Test Case***

Input: 12 books 4 pen

Output: 7

#### ***Answer***

```
s = input()
```

```
total = sum(int(c) for c in s if c.isdigit())
if total > 9:
    result = "Palindrome" if str(total) == str(total)[::-1] else "Not palindrome"
    print(f"{total} {result}")
else:
    print(f"{total} ")
```

**Status :** Correct

**Marks :** 10/10
